

Early Journal Content on JSTOR, Free to Anyone in the World

This article is one of nearly 500,000 scholarly works digitized and made freely available to everyone in the world by JSTOR.

Known as the Early Journal Content, this set of works include research articles, news, letters, and other writings published in more than 200 of the oldest leading academic journals. The works date from the mid-seventeenth to the early twentieth centuries.

We encourage people to read and share the Early Journal Content openly and to tell others that this resource exists. People may post this content online or redistribute in any way for non-commercial purposes.

JSTOR is a digital library of academic journals, books, and primary source objects. JSTOR helps people discover, use, and build upon a wide range of content through a powerful research and teaching platform, and preserves this content for future generations. JSTOR is part of ITHAKA, a not-for-profit organization that also includes Ithaka S+R and Portico. For more information about JSTOR, please contact support@jstor.org.

DISCUSSION AND CORRESPONDENCE

ATMOSPHERIC POLLUTION¹

THE Advisory Committee on Atmospheric Pollution has published its fourth report summing up the observations in the year 1917-1918.

The full lists showing in detail the monthly deposit figures at various stations are not reproduced, inasmuch as these have been already published in the *Lancet*; but full returns from two stations, Newcastle and Malvern, are given; and these give the highest and lowest deposits.

Figures of total solids deposited monthly are given for all stations, 24 in number, the months being on a thirty-day basis.

In many instances the rainfall as measured at these stations did not agree with the amount obtained by the official Meteorological Office gauges but this is easily explained when it is remembered that the gauges of the committee are often on roofs and are thus elevated. The rainfall is given in millimeters, and it would be well if we in the United States would follow this example.

At a given London station the data for the half year, October to March, 1917-1918, were:

Rainfall 43 mm.; tar 0.14 metric ton per square kilometer; carbonaceous matter other than tar 2.18 tons; insoluble ash 3.50; soluble ash 4.15; or total solids 11.41 tons. Of the soluble matter there were 1.46 tons of sulphate, 0.63 tons of chlorine, and 0.05 of ammonia.

No relationship can be discovered between the deposit of insoluble matter and the amount of rainfall. With the soluble matter, however, it is different, and in general it may be said to vary directly as the rainfall. The relation may be roughly expressed by the formula, $S = 0.058 R + 2.5$, where R is the rainfall in mm. and S the deposit of soluble matter in tons per square kilometer. It is not suggested that this expression can be used to find the soluble deposit when the rainfall is known but gives only the general nature of the relationship.

¹ Meteorological Office. Report on Observations 1917-18. Advisory Committee on Atmospheric Pollution, London, 1919.

The report also contains the results of analysis of the rainfall at Georgetown, British Guiana, the nearest land in the direction of the prevailing east-northeast trade winds being the shore of Morocco, distant 3,000 nautical miles. There can be little doubt that the solids contained in the rain waters collected are those normal to the rains of the trade winds, with perhaps some derived from the coastal sea-spray.

The average results over the two years 1916 and 1917 were as follows:

	Solids in Solution, mg./litre
Ca	7.95
Mg	3.44
K	2.77
Na	16.36
Al ₂ O ₃	0.58
Fe ₂ O ₃	1.97
SiO ₂	0.20
Cl ₂	33.93
SO ₄	12.02
CO ₂	9.78
NO ₃	11.57
NH ₄	0.12
	100.69

It is shown that 55 per cent. of the solids in solution in the rainfall are cyclic sea salts, while 45 per cent. must have been derived from atmospheric sources.

The report also contains an account of certain experiments made to determine the best method of measuring continuously the suspended impurity in the air. A. M.

CAROTINOIDS AS FAT-SOLUBLE VITAMINE

My attention has been called to Steenbock's interesting observation, in *SCIENCE* of October 10, that yellow corn and the colored roots, such as carrots and sweet potatoes, are richer in fat-soluble vitamine than white corn and the pigmentless roots and tubers. A number of other instances are noted in which fat-soluble vitamine and carotinoid pigment occur simultaneously. The fact that these relations have led Steenbock to the provisional assumption that the fat-soluble vitamine is one of the carotinoid pigments has prompted me to call attention to a number of cases where this relation apparently breaks down.
